Making personal finance
simpler, more interactive, and
more enjoyable.

BUCKS

Problem

The Problem

Managing money can be difficult, especially for students and young users, as traditional finance applications can feel complicated, overwhelming, and too focused on numbers and reports, making them difficult to stay motivated to use and not always designed around building saving habits. BUCKS was created to make financial management simpler, more engaging, and easier to understand by helping users track their money, manage budgets, save toward their goals, and build better financial habits.

My Solution... meet BUCKS

BUCKS combines personal finance tools with gamification to make managing money more engaging and rewarding. Users can track their income and expenses, manage budgets and view reports, create savings goals, track money owed and debts, complete missions to earn rewards, interact with the Bucks companion, receive financial insights through AI, and customize their Bucks character. The idea is to make managing money feel more like progress than paperwork.

Tech used

Frontend

- Flutter
- Dart
- Material 3
- Provider – state management

Backend

- Supabase
 - Authentication
 - PostgreSQL database
 - Row Level Security
 - Edge Functions

AI

- Google Gemini
- Connected through a Supabase Edge Function

Development

- Git & GitHub
- VS Code
- AI-assisted development using OpenAI and Claude

Challenges

challenge - 1

One of the main challenges was handling Flutter development issues, including layout and RenderBox errors, shared application state, and connecting multiple screens to the same data. I also had to move the app from local storage to Supabase and set up authentication, database security, and backend connections.

challege -2

Another challenge was securely connecting Gemini AI through a Supabase Edge Function. This required understanding how the frontend, database, authentication, and backend services communicate while keeping sensitive credentials protected.

challege - 3

During development, AI-generated code sometimes needed changes before it worked in my actual environment. I learned to run and test the application, read Flutter errors, modify generated implementations, fix configuration issues, and test backend connections. The main lesson I learned is that generated code still needs to be tested and adapted to the real application.

Challenges

challenge - 4

One challenge was keeping user data consistent across different screens. I fixed this by using shared application state and connecting each screen to the same data source.

challege -5

Another challenge was dealing with Supabase and Gemini connection issues. I fixed these by checking the configuration, testing authentication, securing API access through an Edge Function, and verifying the backend connections.

challege - 6

Finally, Flutter errors and AI-generated code sometimes caused unexpected problems. I fixed these by testing the app, reading error messages, modifying the generated code, and checking each feature in the actual application.

What I Would Do Next

BUCKS University

BUCKS

Your money. Your goals. Your progress.

Thank You!!!
